A database management system of the present invention is a database management system (DBMS) that includes a trigger definition, which defines the activation condition and contents of a triggered operation activated upon execution of updating for a table. It further defines an operation where an exception is generated for an update request against the constraint given to the table or a triggered operation.

WHAT IS A RELATIONAL DATABASE MANAGEMENT SYSTEM (RDBMS)?

A relational database management system (RDBMS) is a database engine system based on the relational model. An RDBMS is used to manage large amounts of information and can store huge volumes of data. It supports complex queries and ensures data integrity and consistency. Relational databases are widely used in various applications, from online stores to social media platforms.

The SAP Database contains literally thousands of tables that store information. Some products like ECC and R3 have more than 30,000 tables, while other products like CRM might have fewer than 10,000 tables.

WHAT IS AN OBJECT-RELATIONAL DATABASE MANAGEMENT SYSTEM (ORDBMS)?

An object-relational database management system (ORDBMS) is a database management system that supports both object-oriented and relational data models. ORDBMS allows developers to store and manipulate complex objects and relationships directly in the database, providing a seamless integration of object and relational features.
